TRANSCRIPT :-

Good evening, ma'am. I'm Kishori. So I'm going to explain about my project. So my project is about hospital, patient, and test management portal. So I'm doing the hospital portal website, ma'am. So the main purpose of the hospital portal is to help the hospital staff to manage the patient information and then the test request and the lab results and all. So you may wonder how it's going to work. So this portal process starts from collecting the information from the patient, the basic details like their name, their phone number, and their emergency contact, their address, so on things will be collected as a basic information as a form type. So it can be done by the receptionist or whoever sit in the counter. They will collect this basic information from a patient. So it will be stored as a form for hospital purpose in the hospital portal website itself. So after taking their information, so they'll take a test from a patient, and another form will get filled. So that form will be sent to the lab portal via Dropbox, and that form will require some details, like the blood is taken for what test and what sample the hospital has sent and for what test they are intended to conduct.

So like that, the form needs to be filled. So these are the things on the form. And then after it get retrieved by the lab portal, they do that test and all, and they put the results in the form, and then they store that They store bag that results in the Dropbox itself, which means the hospital portal can get the results and view it and read the patient according to it. Okay, this flow is okay to explain to a normal person, but you are special because you are my faculty, so you also need to hear the technical side. Maybe in that way, I can impress you, ma'am. The technical side is like this is This portal is a website-based application. So the front-end is mainly responsible for providing the screens through which hospital staff manage the patient and test results so that the back-end handles the application logic, authentication, and then the patient and test data, and the communications with the laboratory exchange system. So these are the things that are handled by the back-end. And then the system uses structured CSV data for exchanging the test request and then the results between the hospital and the laboratory.

So this shared exchange layer acts as a communication part between the two independent websites. The hospital uploads the request, and later, they receive the laboratory results. So you may wonder how the hospital and portal access the same Dropbox. So I have created an API key. So I I shared that key with a lab port, like whoever having that lab website. So they also have that key. So we have the same key, so we can access the same Dropbox. So through APIs, we sent the request, and he retrieves that request, and he process the things, and he stores the research back into that Dropbox. And I can

retrieve back the research into my portal, and I can view it so that something's happened. Thank you, ma'am.
